The value model — “a rand is a rand”

Consumers see **one fungible currency balance** (e.g. a ZAR balance) and never encounter blockchain concepts. Under the hood that balance is a *claim* on a reserve the protocol holds — the same shares/reserve idea as ERC-4626 (below). The reserve can be made of more than one backing asset, but the consumer never sees that — they hold the balance as Vault-ledger shares, never the token itself.

	Spend token (e.g. TTZA)	Tradeable ZAR (ZARP, ZARU...)
Represents	Protocol bank cash — fully ZAR-fiat-reserved	Third-party market stablecoins
Nature	Closed-loop, non-tradeable (our own e-money)	Open, composable ERC-20 (Aave, Uniswap)
Crossing in/out	Mint = fiat in; burn = fiat out (settlement)	Acquired by converting cash → tradeable ("cash leaves the ecosystem")
Yield	None on-chain	Yield-bearing — the only source of harvest yield

- **Consumer spend balance is flat 1:1 and earns no yield.** Any vault yield accrues to the **protocol**, not the consumer — so the spend balance never appreciates and stays a true rand.
- **Backing is a protocol property, not per-consumer.** Which asset funds a given fiat settlement or DeFi swap is a treasury decision made at the edges (on-ramp / settlement / conversion) — never on a transfer.
- **Phase 1 is TTZA-only.** The reserve is 100% bank cash (fully reserved, no peg/market risk). Multi-backing, DeFi and consumer-facing tradeable ZAR are designed but not yet enabled.

FX conversion (ZAR ↔ USD)

Consumers can move value between their **Spend (ZAR)** and **Save (USD)** balances on the home screen. These are not ERC-20 transfers to the user's wallet — they are **vault ledger** moves: the backend calls `adminDebit` on one currency claim and `adminCredit` on the other. The consumer never receives TTZA or USDC tokens directly; they hold unified balance shares inside the Vault.
