API

Events are the reporting backbone

Every value-affecting action emits an on-chain **event**. The chain is the source of truth; an **indexer** captures these events and projects them into Postgres so we can query, reconcile and report against them — automated reporting straight off the chain. Postgres is *not* a second ledger: it's a rebuildable index plus the off-chain-only facts that legally can't live on-chain (see below).

Key events (Vault)

Event	Emitted when	Why it matters for reporting
<code>Transferred(from, to, amount, currencyCode)</code>	P2P ledger transfer (incl. cross-border vouchers)	Core value movement; the Travel-Rule line item (joined to identities off-chain)
<code>Deposited(depositor, beneficiary, token, amount)</code>	On-ramp — ERC-20 pulled in	Funds entering the system
<code>Withdrawn(from, to, token, amount)</code>	Off-ramp — ERC-20 pushed out	Funds leaving / merchant settlement
<code>UsdPurchased(buyer, localAmount, localCurrency, usdcReceived)</code>	Local → USDC swap (Uniswap)	FX/treasury reconciliation
<code>RemittanceSettled(from, amount, currencyCode, destination)</code>	Remittance paid out + TreasuryToken burned	Cross-border settlement record
<code>YieldHarvested(currencyCode, yieldDelta, platformCut, userYield, treasury)</code>	Yield swept (Phase 1: 100% to protocol)	Protocol revenue
<code>TrustedCounterpartySet(account, trusted)</code>	Merchant/platform marked trusted	Compliance allow-list audit
