Two ways to send money

Consumers send from the **Vault unified balance** they hold (a ZAR claim). There are two paths, both gasless to the consumer:

	Account-to-account	Via WhatsApp (escrow)
Recipient	Has an account (@tag or 0x wallet)	A phone number — may have no account yet
Mechanism	User-signed <code>Vault.transfer</code> , relayed	<code>Vault.transfer</code> to escrow + claim link
Custody	Moves wallet → wallet directly	Held at custodial escrow until claimed
Gate	On-chain: both parties KYC'd	Sender KYC'd; recipient KYC's on claim

Account-to-account (user-signed, self-custody)

The consumer's **passkey** signs a **Safe transaction** for `Vault.transfer` (recipient, amount, currency, nonce). The backend relays it via `execTransaction` and pays the gas — it can relay or stall, but cannot forge or alter the transfer. The Vault's on-chain gate requires each party to be a KYC'd consumer (or a trusted merchant/treasury), so the rule is enforced by the contract, not the server. See **Gas fees** for how sponsorship works.

Send via WhatsApp (escrow for an unonboarded recipient)

To send to someone who doesn't have an account yet, the value is held in **escrow** and released when they onboard and claim it. The chain holds the value; Postgres holds only the off-chain claim facts (secret hash, beneficiary phone, expiry) — not a second ledger.

1. **Send.** Sender enters a phone number + amount; their passkey signs a `Vault.transfer` to the **custodial escrow address** (a trusted counterparty, so the on-chain gate passes).
2. **Link.** The backend mints a one-time **claim secret** and returns a `wa.me` deep-link the sender taps to message the recipient. The link carries the secret; the secret's hash is stored, never the secret itself.
3. **Claim.** The recipient opens the link → a claim page shows the amount → they **create an account**
